

II. Overview of Methods

Overview of cost methods

- Review general concepts for costing methods
- Case study for HPV vaccination across four countries (Levin et al. 2013)

- Bountiful costing terms and methods.
- Purpose determines the choice of methods.
- Time horizon and timing of costing matters.
- Perspective is about whose costs?
- Scale and scope will affect the total and unit costs.

The main methodological issues in costing health care services

A literature review

- Define the problem
- Identify
- Measure
- Value
- Calculate

Identifying Costs- types of costs

- Direct Health Care costs
 - Treatment or preventative care
 - Hospital, facilities, communities, home
 - Medication, procedures, tests, equipment
- Direct Non-Health Care costs
 - Out-of pocket expenses- transportation, child care
- Productivity costs (Indirect costs)
 - Lost economic productivity due to disability or death

Identifying costs: Basic elements to consider

Cost methods

- Micro-costing methods
 - Bottom up costing
 - Quantify and cost out every input consumed in preventing or treating disease in an individual
- Gross costing or using average costs
 - Allocate the total budget (expenditures) to a particular department or service.
 - Top down costing
- Not mutually exclusive

Analytical approach- Measurement

Step-down accounting

- Health facility level
- Identify major functions or cost centers of the facility

Activity based costing

Published by Oxford University Press in association with The London School of Hygiene and Tropical Medicine Health Policy and Planning 2008;23:408-427 © The Author 2008; all rights reserved. Advance Access publication 28 August 2008 doi:10.1093/heapol/czn018

An activity-based cost analysis of the Honduras **Community-Based, Integrated Child Care** (AIN-C) programme

John L Fiedler,¹* Carlos A Villalobos² and Annette C De Mattos¹

Accepted 12 May 2008

> The Honduras AIN-C programme is a preventive health and nutrition programme of the Honduras Ministry of Health (MOH) that relies on volunteers to help mothers monitor and maintain the adequate growth of young children. A quasi-experimental, design-based evaluation found that the programme achieved near-universal coverage and was effective in improving mothers' child-rearing knowledge, attitudes and practices, including feeding and appropriate caregiving and care-seeking practices for children with diarrhoea and acute respiratory illness. The programme is widely regarded as a model. This study was undertaken to provide the first comprehensive estimates of the cost of the AIN-C programme, with the goal of providing a programme and financial planning tool for Honduras. An additional comparison of study findings was also undertaken to determine the cost of the AIN-C programme's community-based services relative to a similar facility-based service. Expressed in mid-2005 US dollars, the study found that after the programme is phased-in: (1) the annual, recurrent cost per child under 2 years participating in the programme is \$6.43; (2) the annual, incremental budget requirements per child under 2 years participating in the programme are \$3.90; (3) the cost of an AIN-C monthly growth monitoring and counselling session per child is 11% of the cost of a traditional MOH, facility-based growth and development consultation per child; and (4) the effect of mothers substituting AIN-C monitor care for MOH facilitybased care 'saves' 203 000 outpatient visits a year, with a potential cost saving of \$1.66 million, the equivalent of 60% of the recurrent cost of the programme and roughly equal to the annual incremental budget requirements of the programme.

> Sensitivity analysis of the cost estimates is performed to provide insight, for countries considering introducing a similar programme, into how modifications of key characteristics of the programme affect its costs.

Keywords Nutrition, community-based nutrition, cost analysis, health care financing, community participation, volunteer incentives

RESEARCH ARTICLE

Cost of maternal health services in selected primary care centres in Ghana: a step down allocation approach

Maxwell Ayindenaba Dalaba^{1,2*}, Patricia Akweongo¹, Germain Savadogo¹, Happiness Saronga^{1,4}, John Williams² Rainer Sauerborn¹, Hengin Dong^{1,8} and Svetla Loukanova

Abstract

Background: There is a pairoly of Investelpp on the cost of Instith care services in Chain. This point a challenge in the economic evaluation of programmes and intellets policy makes in maning decicions boar allocation of resources to improve health care. This study analysed the overall cost of providing health services in valence primary health contests and how much of the cost is attributed to the provision of antential and delivery services. Methods: The study has a cross-sectional design and quantitative data was collected between July and December 2010 Iveries government run primary health centres in the Katsena-Nankana and Builsa districts of Ghana were random elected for the study. All health-care related com for the year 2010 were collected from a public service providen sengective. The step-down allocation approach recommended by World Health Organization was used for the analysis Results: The average annual cost of operating a health centre was \$136,014 US. The mean costs attributable to ANC and elivery services were \$23,003.05 and \$11,543.05 respectively. Personnel accounted for the largest proportion of cost 5%. Overall, ANC (17%) and delivery (BN) were responsible for less than a quarter of the total cost of operating the walth centres. By disappresating the costs, the average recurrent cost was estimated at \$127,475 US, representing 93,7% of the total cost. Even though material health services are free, utilization of these services at the health centres toularly for delivery (49%), leading to high unit costs. The mean unit costs were \$18 US for an ANC visit and \$63 US for spontaneous delivery:

Conclusion: The high unit costs reflect underutilization of the existing capacities of health centres and indicate the need encourage patients to use health centres. The study provides useful information that could be used for cost fectiveness analyses of maternal and neonatal care interventions, as well as for policy makes to make appropriate lecisions regarding the allocation and sustainability of health care resources.

Revueseds: Cost. Step-down allocation appendich. Anternatal care. Delivery: Maternal health service. Ghana

Background

Reducing maternal and under-five mortality through the use of cost-effective strategies continues to be a challenge, particularly in developing countries. The worldwide maternal mortality ratio (MMR) or the number of women who de during programs, and childbirth per 100,000 live hirths, declined from 299 in 1990 to 202 in 2011, representing a

coupled with the wide range of maternal and neonatal BioMed Central
 BioMed Central
 BioMed Central

Empirical data collection methods

Ingredients approach

 Collect information on quantities and the prices used to value all resources.

Expenditure approach

 Use total expenditure from budget or expense reports from Ministry of Health, implementing organization (i.e. NGO), or donor.

REPORT PREPARED BY NAME: LYDIA AKINYI TITLE: ACCOUNTANT

SIGN LEFE

In practice, it is a combination of both methods

Different way to consider costs categories

- Inputs
- Cost centers/function/activities
- Source of funding
- Level of service delivery
- Start-up costs verses recurrent
- Intervention specific costs verses joint or shared costs
- Combine categories inputs by activity

Cost categories: Inputs

Fixed costs* - remain the same regardless of the quantity of output produced

- Equipment (Vehicles, laboratory equipment, computers)
- Development of training or communication materials
- Overhead (building, utilities, indirect expenses)

Variable costs- depend on the quantity of output.

- Personnel allowances –travel and per diems
- Supplies (IEC materials, drugs and health commodities)
- Transport costs (fuel, maintenance, taxi, public transport)

Valuing capital costs

- Large expenditures that last over one year.
- Could be a hospital, vehicle, laboratory equipment.
- Depreciation is included in costs.
- Also often investments that must occur at the beginning of a project or program.

How to calculate depreciation?

- Equipment costs US\$10,000
- Useful life years of 5 years
 - Financial depreciation is \$10,000/5 = US\$2000 per year
 - But this misses the opportunity cost of investing that capital elsewhere.

Economic depreciation

- Current value: US\$10,000
- Useful life years
- Discount rate 5% (more challenging to calculate the real rate of interest)
- Annualizing factor (standard tables available)= 4.580
- Economic depreciation
 - \$10,000/4.212=\$2,183
- So, if you paid out \$10,000 initially, actually paying more than US\$2000 per year
 - Actual amount will depend on the interest rate.

Valuing volunteer labor

- Community health workers (CHW) provide a lot of support at both the community and health facility level.
- Economic or opportunity cost of next best use of CHW time.

How to value volunteer time?

- Is the cost of volunteer labor zero?
 - Even if unemployed, they could be doing something else (leisure or productive) with their time
- How to value?
 - Use the value of similar employed resources
 - Use a single wage regardless of their actual employment (maybe agricultural wage rate?)

- Administrative data bases
 - From health facility
 - Project expense reports
 - MOH centralized records

- Standardized reporting forms
- Surveys for providers and beneficiaries
- Review of patient charts
- Observation or time-motion studies
- Expert panel
- Published price lists

Health Economic Impact Studies for Translation

Sensitivity analysis

- Process of assessing the robustness of an economic evaluation by considering the effects of uncertainty.
- Consists in:
 - Identifying the (uncertain) variables.
 - Specifying the plausible range over which they should vary.
 - Recalculating results, usually based on:
 - One-way analysis
 - Multi-way analysis
 - Extreme scenario analysis
 - Threshold analysis.
