MASS: Parallel-Computing Library for Multi-Agent Spatial Simulation

Munehiro Fukuda
May 7th, 2010

1. Introduction

This document is written to define the second draft version of the MASS library, a parallel-computing library for multi-agent spatial simulation. As envisioned from its name, the design is based on multi-agents, each behaving as a simulation entity on a given virtual space. The library is intended to parallelize a simulation program that particularly focuses on multi-entity interaction in physical, biological, social, and strategic domains. The examples include major physics problems (including molecular dynamics, Schrödinger's wave equation, and Fourier's heat equation), neural network, artificial society, and battle games.

2. Programming Model

2.1. Components: Places and Agents

“Places” and “agents” are keys to the MASS library. “Places” is a matrix of elements that are dynamically allocated over a cluster of computing nodes. Each element is called a place, is pointed to by a set of network-independent matrix indices, and is capable of exchanging information with any other places. On the other hand, “agents” is a set of execution instances that can reside on a place, migrate to any other places with matrix indices, (thus as duplicating themselves), and interact with other agents as well as multiple places.

An example of places and agents in a battle game could be territories and military units respectively. Some applications may need only either places or agents. For instance, Schrödinger's wave simulation needs only two-dimensional places, each diffusing its wave influence to the neighbors. Molecular dynamics needs only agents, each behaving as a particle since it must collect distance information from all the other particles for computing its next position, velocity, and acceleration.

Parallelization with the MASS library assumes a cluster of multi-core computing nodes as the underlying computing architecture, and thus uses a set of multi-threaded communicating processes that are forked over the cluster and managed under the control of typical message-passing software infrastructure such as sockets and MPI. The library spawns the same number of threads as that of CPU cores per node or per process. Those threads take charge of method call and information exchange among places and agents in parallel.

Places are mapped to threads, whereas agents are mapped to processes. Unless a programmer indicates his/her places-partitioning algorithm, the MASS library divides places into smaller stripes in vertical or in the X-coordinate direction, each of which is then allocated to and executed by a different thread. Contrary to places, agents are grouped into bags, each allocated to a different process where multiple threads keep checking in and out one after another agent from this bag when they are ready to execute a new agent. If agents are associated with a particular place, they are allocated to the same process whose thread takes care of this place.
2.2. Programming Framework
The following code shows a Java programming framework that uses the MASS library to simulate a multi-agent spatial simulation.

```java
import MASS;

class Application {
    public void static main( String[] args ) {
        // get the max simulation time
        int maxTime = Integer.parseInt( args[0] );
        // start a process at each computing node
        MASS.init( args );
        // distribute places and agents over computing nodes
        Places territories = new Places( 1, "Territory", null, 100, 100 );
        Agents troops = new Agents( 2, "Troop", null, territories, 40000 );
        // start cyclic simulation in parallel
        int time = 0;
        int[] destination = new int[2]; dest[0] = 0; dest[1] = 1;
        for ( ; time < MaxTime - 10; time++ ) {
            Object arg = ( Object )( new Integer( time ) );
            territories.callAll( Territory.compute, arg );
            territories.exchangeAll( Territory.exchange, dest );
            troops.callAll( Troop.compute, arg );
        }
    }
}
```
The behavior of the above code is as follows: it synchronizes all processes with MASS.init( ) and has them spawn multiple threads (line 11). The code thereafter maps a matrix of $100 \times 100$ “Territory” places as well as 4000 “Troop” agents over these processes (lines 13 – 16). Each process falls into a cyclic simulation (lines 22 – 29) where all its threads repeat calling the following four functions in a parallel fashion:

- compute( ) of the “Territory” places to update each place object’s status
- exchange( ) of the “Territory” places to exchange data among place objects
- compute( ) of the “Troop” agents to update each agent’s status
- exchange( ) of the “Troop” agents to exchange data among agents

as well as control the “Troop” agents in manageAll( ) so as to move, spawn, terminate, suspend, and resume agents. At the end, all the processes get synchronized together for their termination (line 32).

In the following sections, we will define the specification of “MASS”, “Places”, “Place”, “Agents”, and “Agent”

3. MASS

All processes involved in the same MASS library computation must call MASS.init( ) and MASS.finalize( ) at the beginning and end of their code respectively so as to get started and finished together. Upon a MASS.init( ) call, Each process, running on a different computing node, spawns the same number of threads as that of its local CPU cores, so that all threads can access places and agents. Upon a MASS.finalize( ) call, each process cleans up all its threads as being detached from the places and agents objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>public static void init( String[] args, int nProc, int nThr )</code></td>
<td>Involves nProc processes in the same computation and has each process spawn nThr threads.</td>
</tr>
<tr>
<td><code>public static void init( String[] args )</code></td>
<td>Involves as many processes as requested in the same computation and has each process spawn as many threads as the number of CPU cores.</td>
</tr>
<tr>
<td><code>public static void finalize( )</code></td>
<td>Finishes computation.</td>
</tr>
<tr>
<td><code>public static Places getPlaces( int handle )</code></td>
<td>Retrieves a “Places” object that has been created by a user-specified handle and mapped over multiple machines.</td>
</tr>
<tr>
<td><code>public static Agents getAgents( int handle )</code></td>
<td>Retrieves an “Agents” object that has been created by a user-specified handle and mapped over multiple machines.</td>
</tr>
</tbody>
</table>
4. Places

“Places” is a distributed matrix whose elements are allocated to different computing nodes. Each element, (termed a “place”) is addressed by a set of network-independent matrix indices. Once the main method has called MASS.init( ), it can create as many places as needed, using the following constructor. Unless a user supplies an explicit mapping method in his/her “Place” definition (see 4.2 Place Class), a “Places” instance (simplified as “places” in the following discussion) is partitioned into smaller stripes in terms of coordinates[0], and is mapped over a given set of computing nodes, (i.e., processes).

4.1. public class Places

The class instantiates an array shared among multiple processes. Array elements are accessed and processed by multi-processes in parallel.

<table>
<thead>
<tr>
<th>Public Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Places(int handle, String className, Object argument, int... size)</code></td>
<td>Instantiates a shared array with “size” from the “className” class as passing an Object argument to the “className” constructor. This array is associated with a user-given handle that must be unique over machines.</td>
</tr>
<tr>
<td><code>getHandle()</code></td>
<td>Returns the handle associated with this array.</td>
</tr>
<tr>
<td><code>size()</code></td>
<td>Returns the size of this multi-dimensional array.</td>
</tr>
<tr>

More specifically, inMessages[i] maintains a set of return values from the i\textsuperscript{th} callee.</td>
</tr>
</tbody>
</table>

### 4.2. `public abstract class Place`

“Place” is the base class from which a user can derive his/her application-specific matrix of places. An actual matrix instance is created and maintain within a “Places” class, so that the user can obtain parallelizing benefits from Places’ callAll( ), callSome( ), exchangeAll( ), and exchangeSome( ) methods that invoke a given method of each matrix element and exchange data between each element and others.

<table>
<thead>
<tr>
<th>public Place( Object args )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the default constructor. No primitive data types can be passed to the methods, since they are not derivable from the “Object” class.</td>
</tr>
</tbody>
</table>
4.3. CallMethod

Since method names are user-given, it is quite natural to invoke each array element’s method through Java reflection, which is however intolerably slow for parallel computing. Thus, a selection of methods to call should be preferably done with switch( ), where we need to identify each method as an integer value. callMethod( ) is a user-provided framework that assists the MASS library in choosing a method to call:

Example:

```
1. public static Object callMethod( int funcId, Object args ) {
2.   // automatically called from callAll, callSome, callStatic, exchangeAll, or exchangeSome.
3.   // args may be null depending on a calling method.
4.   return null;
5. }
```
16. switch( funcId ) {
17.   case init: return init( args );
18.   case computeNewWave : return computeNewWave( args );
19.   case exchangeWave : return exchangeWave( args );
20.   case storeWave : return exchangeWave( args );
21.   case startGraphics : return startGraphics( args );
22.   case writeToGraphics : return writeToGraphics( args );
23.   case finishGraphics : return finishGraphics( args );
24.   } 
25.   return null;
26. }
27. 
28. public Object init( Object args ) {
29.   ...;
30. }
31. 
32. public Object computeNewWave( Object args ) {
33.   ...;
34. }
35. 
36. 
4.4. Example 1: Wave2D

The following Wave2D class is a two-dimensional matrix that simulates Schrödinger's wave diffusion. Each “Wave2D” matrix element maintains the six instance variables listed below:

- wave[2]: the current wave height at each matrix element
- wave[1]: the previous wave height
- wave[0]: even the one more previous wave height
- neighbor[0] through to neighbor[3]: the wave height of north/east/south/west neighbors
- time: the current simulation time
- interval: time interval to display the ongoing simulation results

In this Wave2D class, callMethod( ) maps each functionId to the corresponding function (lines 44 – 53); init( ) initializes instance variables of each place or cell (lines 63 – 72); computeWave( ) simulates wave diffusion per time unit (lines 78 – 124); exchangeWave( ) receives wave heights from all the four neighbors (lines 130 – 132); collectWave( ) collects wave heights from all places into place[0][0] that then displays them in graphics (lines 138 – 140); and place[0][0] is in charge of calling startGraphics( ), writeToGraphics( ), and finishGraphics( ) to handle 2D graphics (lines 143 – 244).
int time = 0;
int interval = 0;

// wave height from four neighbors: north, east, south, and west
private final int north = 0, east = 1, south = 2, west = 3;
double[] neighbors = new double[4];

// simulation constants
private final double c = 1.0; // wave speed
private final double dt = 0.1; // time quantum
private final double dd = 2.0; // change in system

// the array size and my index in (x, y) coordinates
private int sizeX, sizeY;
private int myX, myY;

/**
 * Is the constructor of Wave2D.
 * @param interval a time interval to call writeToGraphics()
 */
public Wave2D( Object interval ) {
    this.interval = ((Integer)interval).intValue();
}

public static Object callMethod( int funcId, Object args ) {
    switch( funcId ) {
    case init_: return init( args );
    case computeNewWave_: return computeNewWave( args );
    case exchangeWave_: return (Object)exchangeWave( args );
    case collectWave_: return (Object)collectWave( args );
    case startGraphics_: return startGraphics( args );
    case writeToGraphics_: return writeToGraphics( args );
    case finishGraphics_: return finishGraphics( args );
    }
    return null;
}

public Object init( Object args ) {
    sizeX = size[0]; sizeY = size[1]; // size is the base data members
    myX = index[0];  myY = index[1];  // index is the base data members
    // reset the neighboring area information.
    neighbors[north] = neighbors[east] = neighbors[south] =
        neighbors[west] = 0.0
    return null;
}

/**
 * Since size[] and index[] are not yet set by
 * the system when the constructor is called, this init() method must
 * be called "after" rather than "during" the constructor call
 * @param args formally declared but actually not used
 */
public Object init( Object args ) {

    neighbors.add( west );
5. Agents

“Agents” is a set of execution instances, each capable of residing on a place, migrating to any other place(s) with matrix indices, and interacting with other agents as well as multiple places.

5.1 public class Agents

Once the main method has called MASS.init( ), it can create as many agents as needed, using the Agents( ) constructor. Unless a user supplies an explicit mapping method in his/her “Agent” definition (see 5.2 public abstract class Agent), “Agents” distribute instances of a given “Agent” class (simplified as agents in the following discussion) uniformly over different computing nodes.

<table>
<thead>
<tr>
<th>Public</th>
<th>Agents( int handle, String className, Object argument, Places places, int initPopulation )</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Instantiates a set of agents from the “className” class, passes the “argument” object to their constructor, associates them with a given “Places” matrix, and distributes them over these places, based the map( ) method that is defined within the Agent class. If a user does not overload it by him/herself, map( ) uniformly distributes an “initPopulation” number of agents. If a user-provided map( ) method is used, it must return the number of agents spawned at each place regardless of the initPopulation parameter. Each set of agents is associated with a user-given handle that must be unique over machines.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>public int</th>
<th>getHandle( )</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Returns the handle associated with this agent set.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>public int[]</th>
<th>nAgents( )</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Returns the total number of agents.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>public void</th>
<th>callAll( int functionId )</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Calls the method specified with functionId of all agents. Done in</td>
</tr>
</tbody>
</table>
public void callAll( int functionId )
    Calls the method specified with functionId of all agents. Done in parallel among multi-processes/threads.

public void callAll( int functionId, Object argument )
    Calls the method specified with functionId of all agents as passing an Object argument to the method. Done in parallel among multi-processes/threads.

public Object[] callAll( int functionId, Object[] arguments )
    Calls the method specified with functionId of all agents as passing arguments[i] to agent[i]'s method, and receives a return value from it into Object[i]. Done in parallel among multi-processes/threads. The order of agents depends on the index of a place where they resides, starts from the place[0][0]...[0], and gets increased with the right-most index first and the left-most index last.

public void manageAll( )
    Updates each agent’s status, based on each of its latest migrate(), spawn(), kill(), sleep(), wakeup(), and wakupAll() calls. These methods are defined in the Agent base class and may be invoked from other functions through callAll and exchangeAll. Done in parallel among multi-processes/threads.

public void sortAll( boolean descending )
    Sorts agents within each place in the descending order of their “key” values.

public void exchangeAll( int handle, int functionId )
    Allows each agent to call the method specified with functionId of all the other agents residing within the same place as where the calling agent exists as well as belonging to the agent group with “handle”. The caller agent’s outMessage, (i.e., an Object) is a set of arguments passed to the callee’s method. The caller’s inMessages[], (i.e., an array of Objects) stores values returned from all callee agents. More specifically, inMessages[i] maintains a set of return values from the i\textsuperscript{th} callee.

The following example of code fragment creates an args[0] x args[0] matrix over multiple processes (line 11), distributes a “RandomWalk” agent every four places of this matrix (lines 12 – 13), and simulates random walk of these agents over the matrix using many threads (lines 16 – 19).

```java
1: import MPI;
2: import MASS;
3: class RandomWalkDriver {
4:     public void static main( String[] args ) {
5:         MASS.iinit( args );
6:         int size = Integer.parseInt( args[0] );
7:         int maxTime = Integer.parseInt( args[1] );
8:         Places matrix = new Place( 1, "Matrix", null, size, size );
9:         Agents walkers = new Agents( 2, "RandomWalk", null, matrix,
10:                                        size*size / 4 );
11:         Places matrix = new Place( 1, "Matrix", null, size, size );
12:         Agents walkers = new Agents( 2, "RandomWalk", null, matrix,
13:                                        size*size / 4 );
14:         
```
5.2 public abstract class Agent

“Agent” is the base class from which a user can derive his/her application-specific agent that migrates to another place, forks their copies, suspends/resumes their activity, and terminate themselves.

<table>
<thead>
<tr>
<th>public</th>
<th>Agent( Object args )</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is the default constructor. No primitive data types can be passed to the methods, since they are not derivable from the “Object” class.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>public Place</th>
<th>place</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Points to the current place where this agent resides.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private int[]</th>
<th>index</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is an array that maintains the coordinates of where this agent resides. Intuitively, index[0], index[1], and index[2] correspond to coordinates of x, y, and z, or those of i, j, and k.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Public final int</th>
<th>agentId</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is this agent’s identifier. It is calculated as: the sequence number * the size of this agent’s belonging matrix + the index of the current place when all places are flattened to a single dimensional array.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Public final int</th>
<th>parented</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is the identifier of this agent’s parent.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private int</th>
<th>newChildren</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is the number of new children created by this agent upon a next call to Agents.manageAll().</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private Object[]</th>
<th>arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is an array of arguments, each passed to a different new child.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private boolean</th>
<th>alive</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is true while this agent is active. Once it is set false, this agent is killed upon a next call to Agents.manageAll().</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private int</th>
<th>eventId</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>indicates which event this agent sleeps on. The eventId should be between 1 and 10. All the other numbers mean that the agent does not sleep.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>private int</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Is the value used to sort agents.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>public static int</th>
<th>map( int maxAgents, int[] size, int[] coordinates )</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Returns the number of agents to initially instantiate on a place indexed with coordinates[]. The maxAgents parameter indicates the number of agents to create over the entire application. The argument size[] defines the size of the “Place” matrix to which a given “Agent” class belongs. The system-provided (thus default) map( ) method distributes agents over places uniformly as in: maxAgents / size.length</td>
</tr>
<tr>
<td></td>
<td>The map( ) method may be overloaded by an application-</td>
</tr>
</tbody>
</table>
**MASS: Parallel-Computing Library for Multi-Agent Spatial Simulation**

**public static int**

```java
map( int maxAgents, int[] size, int[] coordinates )
```

Returns the number of agents to initially instantiate on a place indexed with coordinates[]. The maxAgents parameter indicates the number of agents to create over the entire application. The argument size[] defines the size of the “Place” matrix to which a given “Agent” class belongs. The system-provided (thus default) map( ) method distributes agents over places uniformly as in:

```
maxAgents / size.length
```

The map( ) method may be overloaded by an application-specific method. A user-provided map( ) method may ignore maxAgents when creating agents.

**public boolean**

```java
migrate( int... index )
```

Initiates an agent migration upon a next call to Agents.manageAll(). More specifically, migrate( ) updates the calling agent’s index[].

**public void**

```java
create( int numAgents, Object[] arguments )
```

Spawns a ‘numAgents’ of new agents, as passing arguments[i] to the i-th new agent upon a next call to Agents.manageAll(). More specifically, create( ) changes the calling agent’s newChildren.

**public void**

```java
kill( )
```

Terminates the calling agent upon a next call to Agents.manageAll(). More specifically, kill( ) sets the “alive” variable false.

**public boolean**

```java
sleep( int eventId )
```

Puts the calling agent to sleep on a given eventId whose value should be 1 through to 10. If eventId is not in the range of 1 through to 10, the agent will not be suspended. The sleep( ) function returns true if the agent is suspended successfully.

**public void**

```java
wakeup( int eventId )
```

Wakes up only one agent that is sleeping on a given eventId within the same place as where this calling agent resides.

**public void**

```java
wakeupAll( int eventId )
```

Wakes up all agents that are sleeping on a given eventId within the same place as where this calling agent resides.

**public void**

```java
setKey( int value )
```

Substitutes the calling agent’s “key” variable a given value. It is used for sorting agents within the same place.

**public Object**

```java
callMethod( int functionId, Object[] arguments )
```

Is called from Agents.callAll( ) and exchangeAll( ), and invokes mass_0, mass_1, mass_2, mass_3, or mass_4 whose postfix number corresponds to functionId. An application may override callMethod( ) so as to direct Agents to invoke an application-specific method.

**public Object[]**

```java
outMessages
```

Stores a set arguments to be passed to a set of remote-cell functions that will be invoked by exchangeAll( ) in the nearest future.

**public Object[]**

```java
inMessages
```

Receives a return value in inMessages[i] from a function call made to the i-th remote cell through exchangeAll( ).
5.3. Example 2 RandomWalk

The following RandomWalk simulates the walk of agents, each searching for and moving to the least crowded place over a two-dimensional matrix. Starting from RandomWalk.main( ), the program instantiates a two dimensional “Land” array, and populates agents over a small square in the middle of this land (lines 11 – 29). Thereafter, the main( ) function initializes the relative X and Y coordinates of each cell’s four neighbors ( lines 31 – 37), and finally goes into a cyclic simulation (lines 38 – 47) where each cell exchanges #agents with its four neighbors and each agent migrates to a neighbor with the least agents. This cyclic simulation is performed in parallel with multiple processes, each with multiple threads. The class “Land” defines this two-dimensional simulation space (lines 54 – 98) and the class “Nomad” describes each agent’s behavior (lines 99 – 168).

```java
1. import MASS.*;             // Library for Multi-Agent Spatial Simulation
2. import java.util.Vector;   // for Vector
3.
4. // Simulation Scenario
5. public class RandomWalk {
6.    /**
7.     * Starts a RandomWalk application with the MASS library
8.     * @param receives the Land array size, the number of initial agents, and
9.     *     the maximum simulation time.
10.    */
11.   public static void main( String[] args ) {
12.      // validate the arguments
13.      if ( args.length != 3 ) {
14.          System.err.println( "usage: " +
15.              "java RandomWalk size nAgents maxTime" );
16.          System.exit( -1 );
17.      }
18.      int size = Integer.parseInt( args[0] );
19.      int nAgents = Integer.parseInt( args[1] );
20.      int maxTime = Integer.parseInt( args[2] );
21.      
22.      // start MASS
23.      MASS.init( args );
24.      
25.      // create a Land array.
26.      Places land = new Places( 1, "Land", null, size, size );
27.      
28.      // populate Nomad agents on the land.
29.      Agents nomad = new Agents( 2, "Nomad", null, land, nAgents );
30.      
31.      // define the four neighbors of each cell
32.      Vector<int> neighbors = new Vector<int>( );
33.      int[] north = { 0, -1 }; neighbors.add( north );
34.      int[] east  = { 1,  0 }; neighbors.add( east  );
35.      int[] south = { 0,  1 }; neighbors.add( south );
36.      int[] west  = { -1, 0   }; neighbors.add( west  );
37.      
38.      // now go into a cyclic simulation
39.      for ( int time = 0; time < maxTime; time++ ) {
40.          // exchange #agents with four neighbors
41.          land.exchangeAll( 1, Land.exchange, neighbors );
42.          land.callAll( Land.update );
43.          
44.          // move agents to a neighbor with the least population
45.          nomad.callAll( Nomad.decideNewPosition );
46.          nomad.manageAll( );
47.      }
48.    }
```
// finish MASS

    return 0;
}
MASS: Parallel-Computing Library for Multi-Agent Spatial Simulation

6. Implementation Plan

Although we used Java to draft the specification of the MASS library and its example code, the actual library implementation can be carried out in not only Java but also C/C++ so as to cover various applications domains.
The following NSF funding programs are possible options to ask support for this library implementation and extension to any existing and new projects such as UW Bothell’s AgentTeamwork and UWB-Shizuoka Sensor-Grid.

1. Computer and Network Systems (CNS) Core Programs
   Deadline: mid December annually

2. Computing and Communication Foundations (CCF) Core Programs
   Deadline: mid December annually

7. Credits

The very first draft specification was written in support from PDM&FC, Lisbon, Portugal during my sabbatical in 2008 – 2009 and may be used for their grant proposal submitted European Commission.
