

What Is Salmonid Habitat Intrinsic Potential (IP) Modeling

An Overview of Fundamental Aspects

Investigating critical issues in forestry and coastal marine resources

Salmonid IP Models Are Spatially Explicit Habitat Potential Models

IP Models relate habitat preferences to landscape features

- ▣ The landscape features are stream **reaches**
- ▣ Salmonid life cycle habits define **habitat preferences**

IP Models estimate **potential** habitat quality and quantity

- ▣ Score for each **habitat suitability curve** in a set
- ▣ Combined **IP score** assigned to each stream reach
- ▣ Scored reaches analyzed using GIS software or other means

IP Models Relate Habitat Preferences to Stream Reaches

Influences, characteristics, properties, and parameters can be

- ▣ **Intrinsic** - Difficult to change, innate
- ▣ **Extrinsic** - Easy to change, ephemeral

Stream reaches are identified by intrinsic **properties**

- ▣ **Characteristics** are built from geomorphic, hydrologic, topologic and climate **influences**
- ▣ **Characteristics** determine **properties** of reaches
- ▣ Examples: channel width, gradient, and mean annual flow
- ▣ This hierarchy is intended **as a guide** for understanding the underlying structural relationships of model **parameters**

IP Models Relate Habitat Preferences to Stream Reaches

Spawning, rearing, migration, or other life cycle habits are selected for modeling

- ▣ More than one **may** be modeled

Habitat preferences are represented as **suitability** and are scored against **parameters** on a curve

- ▣ Parameters are composed of **one or more** reach properties
- ▣ Range of **parameter values** on **x-axis** of curve
- ▣ Range of **suitability scores** on **y-axis** of curve
- ▣ **Break points** are created where a suitability score is plotted against a parameter value

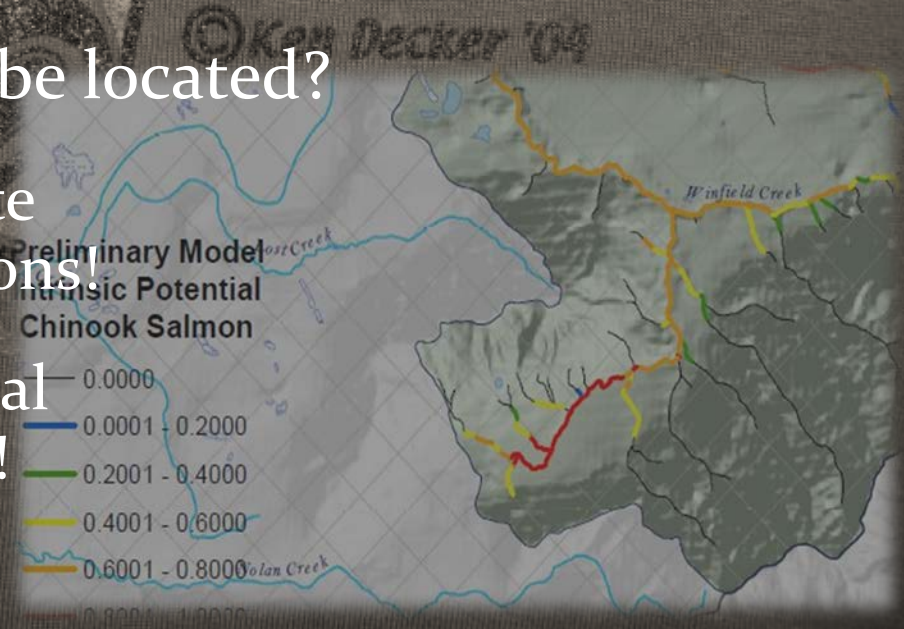

IP Models Hypothesize About Potential Habitat Suitability

What would the **current** river system be like if human influences were removed?

- ▣ Barriers such as culverts and dams
- ▣ Pollutants such as nonpoint and sewer discharge
- ▣ Impacts such as clear cuts and development

Where would the best habitat be located?

- ▣ IP Models do **not** simulate historical habitat conditions!
- ▣ They **do** simulate potential future habitat conditions!

Salmonid IP Models Identify Priorities

What salmon restoration projects would be most effective?

- ▣ Which ones would provide more “bang for the buck”?
- ▣ Which ones would have the widest impact?

What fish management strategies would be most effective?

- ▣ Where and when should they be applied?

What conservation efforts would be most effective?

- ▣ Where should they be applied?

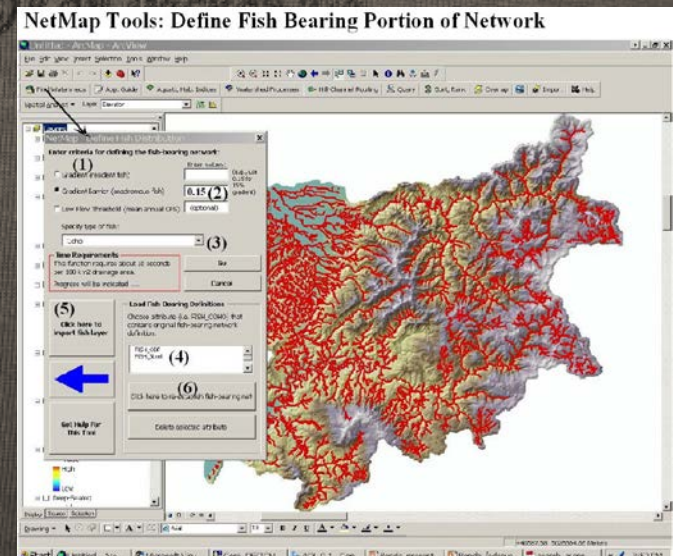

IP Models provide well grounded data to any cost / benefit analyses.

Setting The Stage: Constructing the Fish Bearing Network

Cutoff variables limit the fish bearing network

- Define upstream limits
 - Elevation, channel width, maximum gradient
- Define downstream limits
 - Tidal elevation, salinity
- Define local natural limits
 - Natural barriers
- May be proxies for other less accessible variables

Relating Reaches To Habitat Preferences: Building Intrinsic Parameters

Intrinsic parameters are constructed by fish biologists

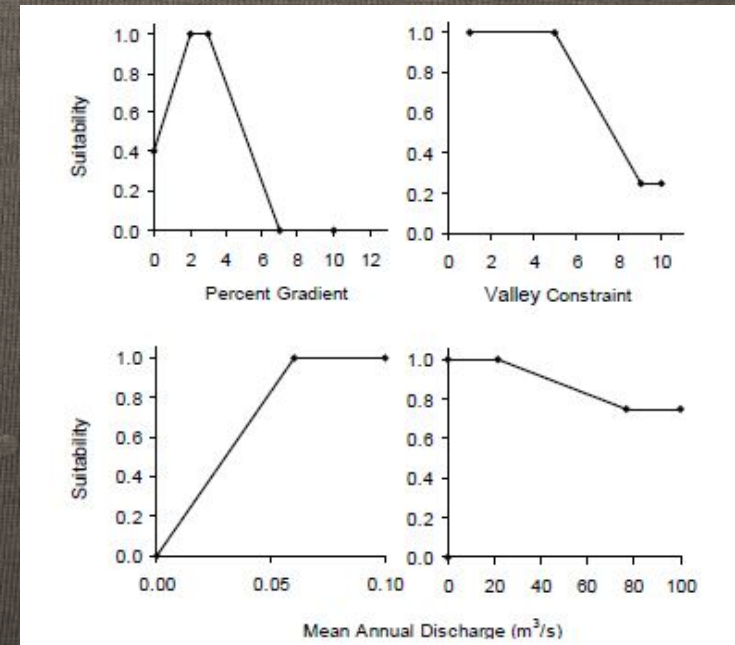

- ▣ Deemed most important factors affecting habitat suitability
- ▣ Composed of one or more reach properties
 - Example: channel confinement is ratio of floodplain width to channel width
 - Example: gradient as reach property **and** intrinsic parameter
- ▣ Maybe be proxy for other parameters
 - Proxy for stream complexity (not well suited for reach based analysis)

Generating Habitat Suitability (HS) Curves

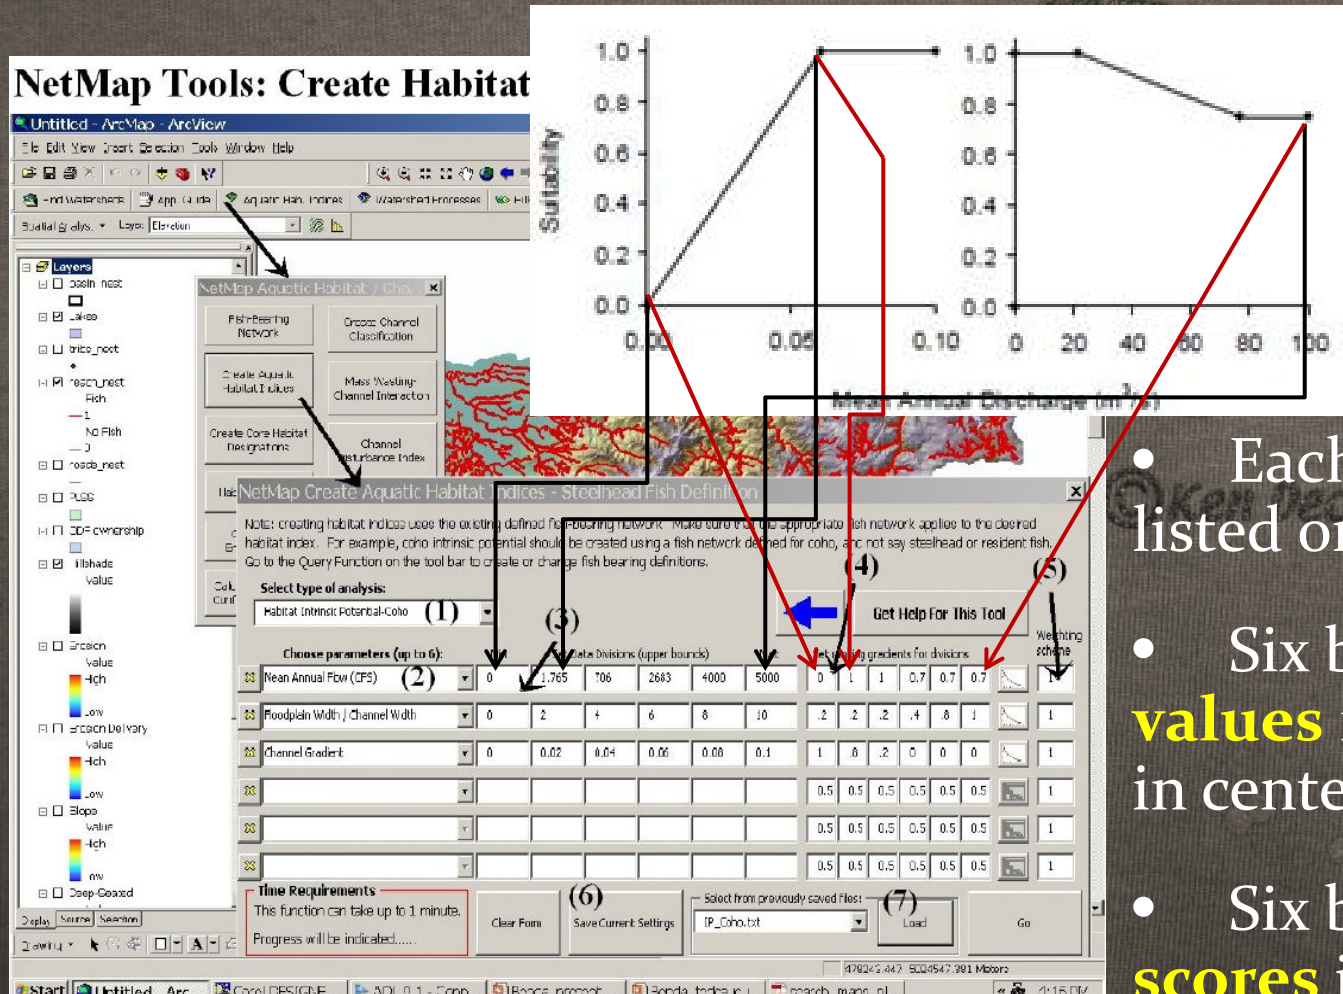

HS curves depict how habitat suitability scores change across a range of intrinsic parameter values

- Suitability index is on **y-axis**
 - value ranges from **zero** (unsuitable) to **one** (best possible)
- Parameter range is on **x-axis**
 - Minimum (usually zero) to maximum limit
- Biologists estimate impact on habitat suitability at each step in the parameters' range
 - Break points make up the curve

Loading HS Curves Into NetMap

Six break point **x** parameter values and **y** suitability scores on the curve for each parameter are loaded into NetMap.

- Each parameter is listed on the left (2)
- Six break point **x values** in black entered in center (6)
- Six break point **y scores** in red entered at right (7)

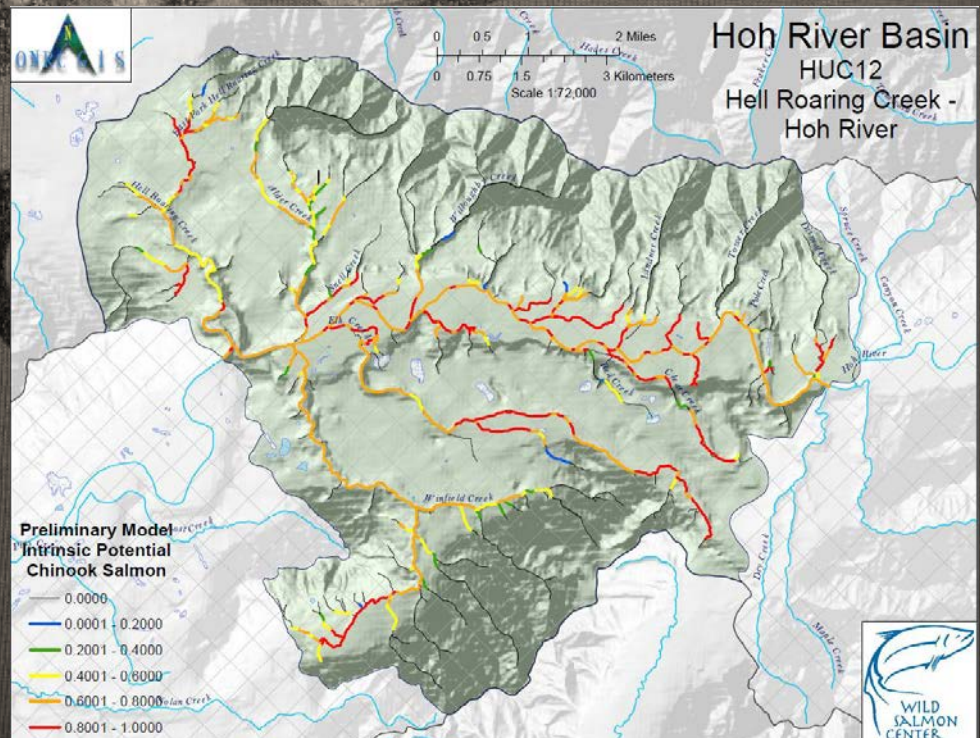

Running The NetMap Model

In NetMap, the model is run on the fish bearing network which defines the spatial extent.

- ▣ Model generates spatial data with **Intrinsic Potential (IP)** scores for each reach
- ▣ Fish biologists and local experts use field knowledge to critique results

Example is model output for one level 6 subwatershed

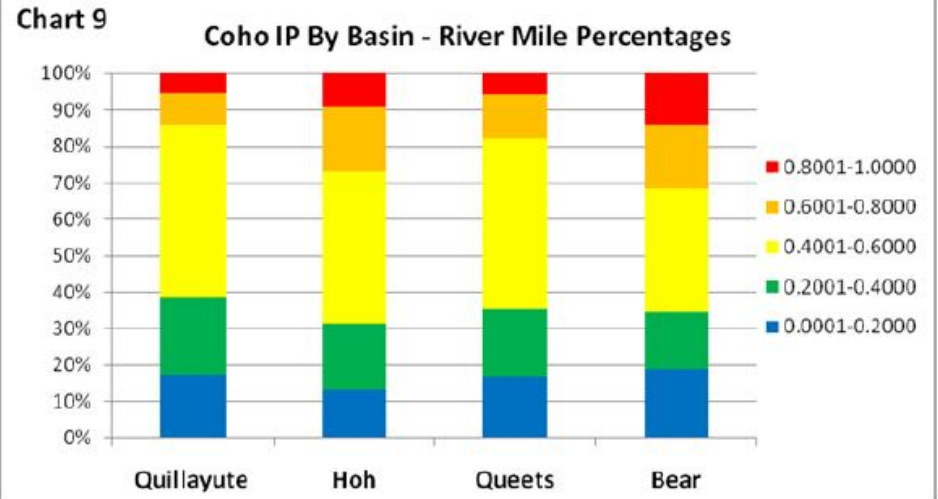

- Note five categories or **bins** for IP scores plus zero
- **Binning** distinguishes gradations of IP scores
- Each species may require a different binning scheme

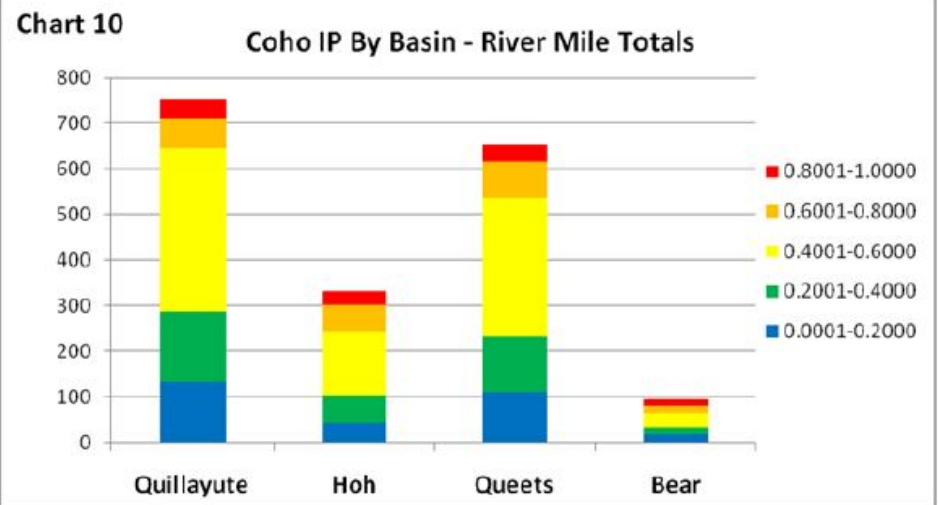

Analyzing The Model Results: Binned Values

A typical analysis of habitat quality by watershed

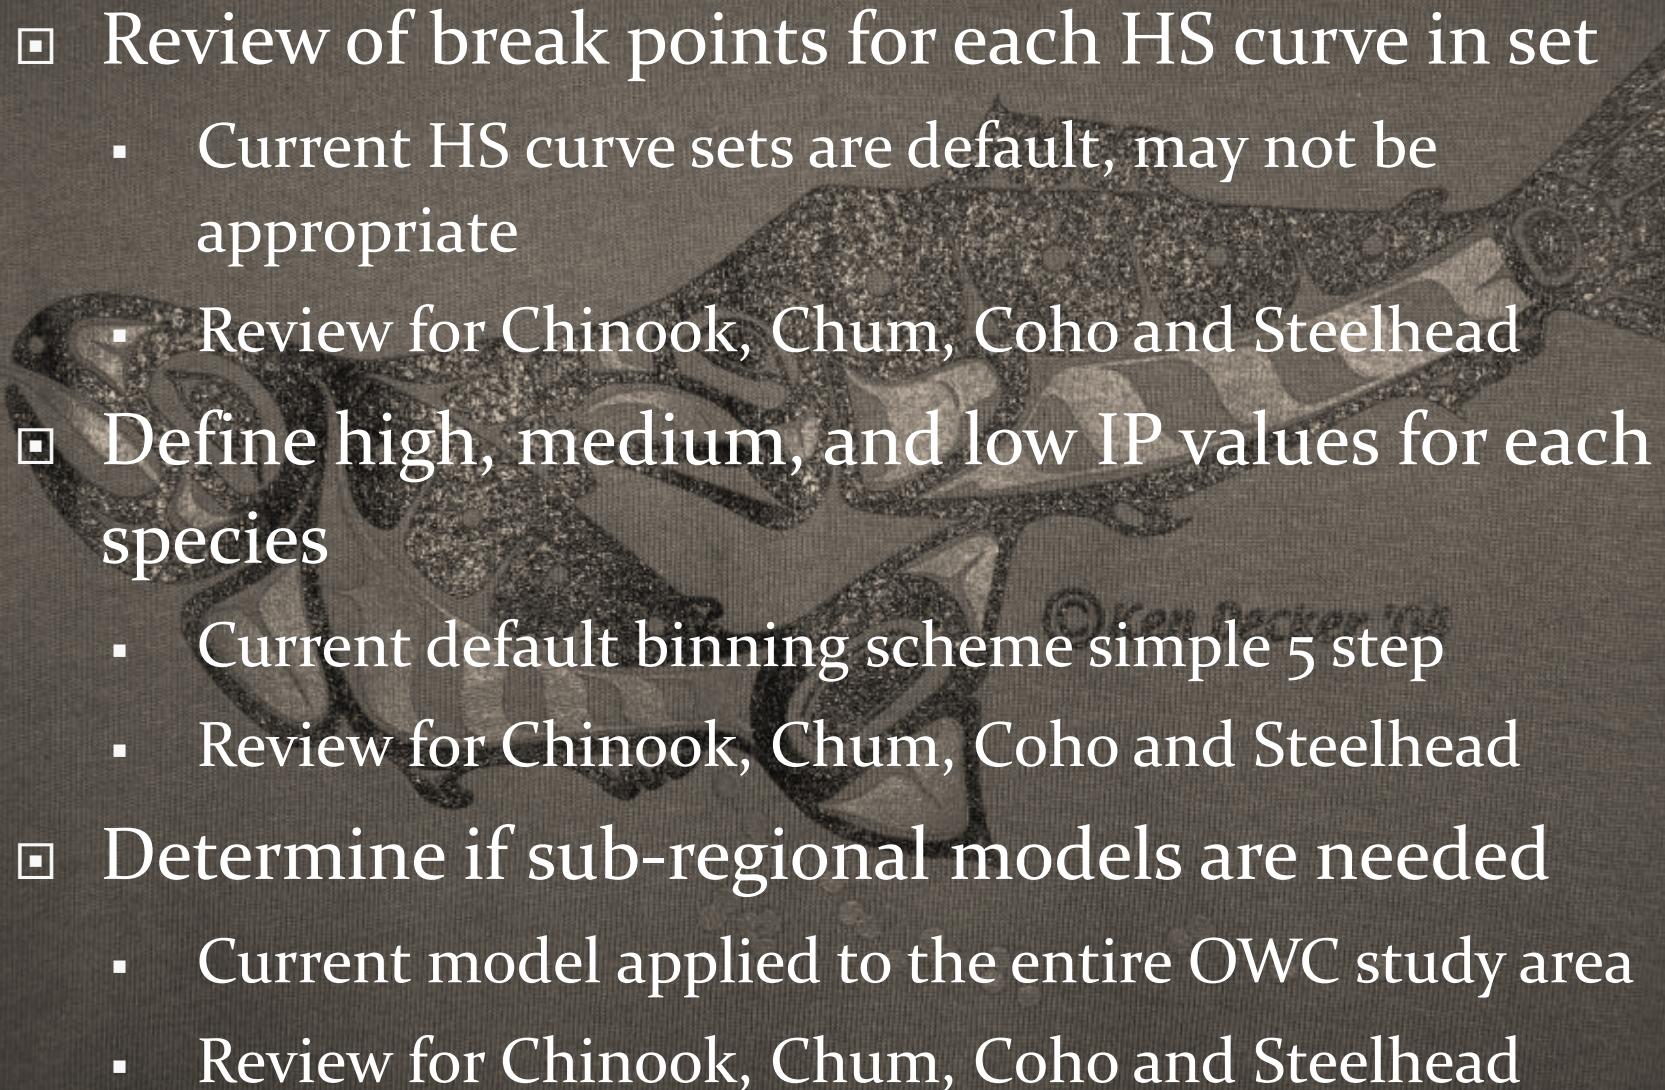

▣ Top chart: share of total river miles in each watershed by **binned** IP value

▣ Bottom chart: river mile totals for each **binned** IP value by watershed

Tasks for IPM Peer Review

- 
- ▣ Review of break points for each HS curve in set
 - Current HS curve sets are default, may not be appropriate
 - Review for Chinook, Chum, Coho and Steelhead
 - ▣ Define high, medium, and low IP values for each species
 - Current default binning scheme simple 5 step
 - Review for Chinook, Chum, Coho and Steelhead
 - ▣ Determine if sub-regional models are needed
 - Current model applied to the entire OWC study area
 - Review for Chinook, Chum, Coho and Steelhead
