15. Supplementary Notes:

16. Abstract This report provides estimates of the value of outputs, inputs, and markets served by elements of the transportation services industries in Washington State. The study is an extension of <u>The Washington State Input-Output Study for 1982</u> by the inclusion of a detailed examination (by mode of transport) of purchase-sales relationships. Portions of the report address the conceptual and empirical problems in measuring regional interindustry flows in the transport sectors, and particularly the methodological limitations surrounding synthetic I/O models and survey approaches. A gross flows matrix (62 x 64), direct requirements table (59 x 59), and output multiplier matrix with households endogenous are included. Impact multipliers (value added, earnings, jobs) for the transport sectors are included. The study provides estimates of the economic importance of the transportation industry in Washington. The model facilitates the evaluation of the impact of autonomous changes in the demand for transportation services upon the rest of the regional economy, and the estimation of the impacts of changes in the rest-of-the-economy upon the demand for transportation services in Washington State.

THE WASHINGTON STATE TRANSPORT I/O MODEL

by
Philip J. Bourque
University of Washington

Summary

This report describes the formulation of a transport-oriented input-output model for Washington state as an extension of a more general study published earlier this year.* In 1982 more than 80,000 jobs, representing 3.9% of all state employment, were directly involved in providing transportation services on a commercial basis. It accounts for nearly 5% of the gross domestic product of Washington State. Such statistics attest to the importance of the industry in this state. Yet, very little is known about the value of its output, its markets, or its procurement impacts. This report attempts to provide estimates of such activities, by mode of transport, and impact multipliers associated with the demand for transportation services.

The central foci of attention are the conceptual and empirical difficulties associated with measuring input-output flows of the transport sector within the Washington economy. The Transportation Services sector in any regional input-output model poses significant problems related to the meaning of the term "regional" in a sector in which the factors of production are mobile, of the appropriate definition of included activity, and how its regional output should be measured.

This paper begins by forming a geographic model of the activities

* Bourque, Philip J. The Washington State Input-Output Study for 1982, Graduate School of Business Administration, University of Washington (March 1987).

of a regional transportation sector compatible with the rules of input-output accounting. How other studies measure transportation sector flows is discussed briefly. There follows a description of the empirical procedures used for estimating output, inputs, and sources of revenue for the Washington Transportation Services sectors. From the gross flows table, some summary observations about the dimensions of the industry are made. The report concludes with a discussion of transport multipliers.

The Transport Sector: Problem of Regional Identity

For purposes of an input-output analysis it is necessary to develop estimates of the value of output of each industry sector, the distribution of outlays for operating inputs to support its output, and the disposition of that output to the various industries which use its product. These estimates of output, purchases, and sales must be within the context of conventions appropriate to regional input-output accounting. These accounting conventions are broadly derived from the principles of national income accounting. However, the particulars of their application to regional accounts, and to the accounts for the Transportation Services sector in particular, have not yet been examined (let alone standardized) in significant detail.

For the Transportation Services sector of a regional economy, the estimation of output, purchases, and markets present numerous conceptual and empirical problems. In the first instance is the difficulty of defining the output of the Transportation Services sector in a regional context. In principle, the output of a sector is measured by the operating revenue generated by the resources (capital, labor) employed within the region. However, important elements of the Transport

Services sector (e.g., rail, air, water) are institutionally organized and operated on a systems basis which cross regional boundaries. The factors of production engaged within the Transportation Services sector are spatially mobile and their "place of output" cannot be as easily defined as those of a factory. The inter-regional mobility of capital (e.g., airplanes) and labor (pilots) suggest that the very notion of regional identity of output is to some extent inappropriate. However, the demand for comprehensive economic information at the state level, where economic planning and policy analysis is so important, justifies the search for an accommodation to what (in the case of certain transportation services) is an unnatural geographic entity for economic accounting.

A second complication is that input-output accounting conventions specify that the flows of goods and services be measured in terms of producers' prices. This assures that the revenue received by a producer equals outlays by purchasers. To insure this equating of the cost of a purchaser to the revenue of the producer, transportation and distribution margins must be treated as a purchaser's expense. The rule may be succinctly put: the purchaser pays the freight. This accounting rule is often inconsistent with actual market transactions since goods are frequently sold by producers on a delivered cost basis. In reality, purchasers of goods often do not know how much of the markup over producers' costs is associated with the prices they pay for inputs. Transporters of goods do not usually know the identity of the users of goods since they pass through marketing channels, nor do purchasers know how much of the value of their outlays represent transport costs for the same reason. This makes the use of surveys of transportation agents

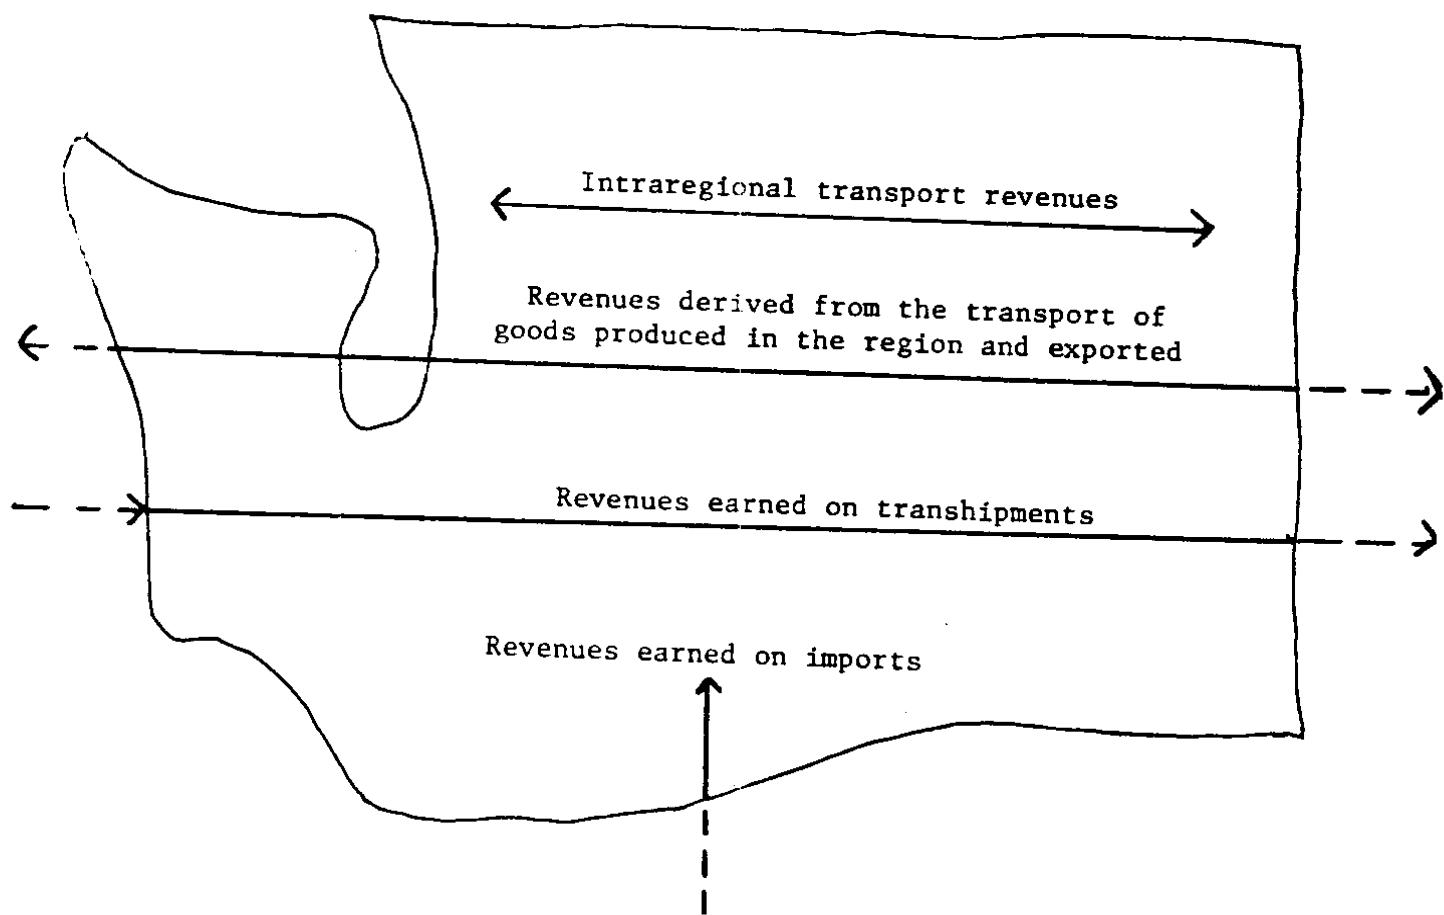

(for whom did you provide this service?) or recipients of delivered goods (how much of your purchase cost represented transport charges?) virtually meaningless.

Combining the notions that (a) the state is a desired geographic entity for the measurement of output, input, and markets, (b) the operating revenue of a sector is defined by its association with the resources employed within the state, and (c) the purchaser pays the freight, then a simple geographic model (Figure 1) of the Transport sector may be sketched. According to this scheme, the services provided by -- and hence operating revenues attributed to -- the Transport services sector are derived from four sources, namely

- (a) Revenue from intra-regional traffic
- (b) Revenue from movement of goods produced within the region and exported to other regions
- (c) Revenue from movement of goods transshipped thru the region
- (d) Revenue from movement of goods produced outside the region and consumed within the region

The revenue sources shown in Figure 1 by solid lines represent revenue of the Washington Transportation Services sector because such movements take place within the state. Such transport revenues are either costs to purchasers within the state or they are costs attributable to out-of-state purchasers (the purchaser pays the freight). The dashed lines represent out-of-state transport services. These costs are imported transportation services by Washington purchasers, or they are non-Washington transportation services chargeable to out-of-state purchasers. Since input-output accounts are concerned with real flows, where and how payment for transport services

Figure 1: Revenue Sources of the Washington Transportation Services Sector

is made, the purely financial aspects (for example, ticket sales of airlines), are not germane. It is the revenue earned by the transport services provided by the resources employed within the region (and by whom and for whom) and the outlays to support that level of activity which count. In this scheme, the state of registration of capital (e.g., vehicle registration or vessel home port), or place of residence of labor, are not relevant; place of work is the dominating criterion.

Since transport carriers do not identify sources of revenue or operating expenditures within narrowly defined political borders, such a revenue scheme may appear quite artificial. As previously observed, transport carriers operate on a system basis, and systems may cross state lines. It is not a question of what portion of a carrier's operating revenue is received within the region, but what part could conceivably be apportioned to a region as a result of the labor and capital employed therein.

The principal value in the diagrammatic model of revenue flows is that it recognizes transportation services are associated with exports, imports, transshipments, and intra-regional movements. Unlike some methods of accounting for the activity of transport services, the model developed here recognizes that cross-hauling, or the simultaneous import and export of transportation services, occurs within a region. Out-of-state transport services associated with procurement by Washington business represent an import of transport services. Washington transport services rendered out-of-state buyers represents dollars of revenue derived from the export of transport services.

Alternative Approaches to Measurement

Given that regional input-output modelling has been the dominant framework in regional economic analysis for the past several decades, one might expect that accounting standards for measuring regional transportation services would have evolved. Yet, a survey of various input-output studies indicates only cursory attention to the measurement problems in the Transport Services sector.

There are two basic methods of construction of regional input-output tables. One of these is called the survey approach, although practically all such studies depend only partly upon surveys. Its identifying characteristic is that it exploits available regional information and minimizes reliance upon national relationships. However, such I/O studies have been extremely vague as to how information from field surveys facilitates the identification of export and import flows in the Transport Services sector. A perusal of several well-known regional studies of the survey variety were mute about how such survey information is actually used to measure the distribution of regional transport, output or sources of transportation industry revenue within a region. The reknown West Virginia study (1965) scarcely mentions the uniqueness of the transport sectors. Other survey-type studies, including those for Kansas (1965), St. Louis region (1967), and Tennessee (undated), do not discuss attendant details sufficiently to provide procedures others could emulate. The landmark Philadelphia study (1959) explicitly recognizes the desirability of distinguishing between transport revenues earned on intra-regional as contrasted to inter-regional shipments; recognizing the extreme difficulty of

obtaining appropriate information from transportation enterprises, that study used national transport cost coefficients, apparently unmodified.

As an alternative to survey models, less exacting, speedier, and low-cost non-survey techniques have dominated regional I/O modelling in recent years. I call these "synthetic" methods because such models are derived by manipulating of national input-output relationships to estimate regional flows and their derivative multipliers. Typically, as in RIMS II, simple location quotients (LQ's) are applied to national procurement patterns to derive proxy values for direct regional input-output coefficients. From the direct coefficients, estimates of multiplier relationships and inter-industry transactions may then be derived.

Synthetic models begin with the assumption that the total (or technical) procurement patterns in each sector in every region are identical to national purchase patterns, differing only in scale. This is patently untrue for every sector, even at the most highly detailed level of sector disaggregation for which national coefficients are available. Two examples of the technical structure from Washington State are illustrative: Washington's aircraft industry (dominated by Boeing) is largely final assembly work whose inputs differ significantly from those of aircraft parts producers; electricity production in Washington is uniquely dependent upon hydro-electric power sources with negligible inputs of coal, petroleum, or gas.

The use of national coefficients as the initial point of departure for estimating regional input patterns also adopts the national conventions in respect to the treatment of foreign imports. In the national table, comparable foreign imports (those with a domestically

produced counterpart) are treated as an addition to the output of the domestic producing industry and distributed to various users in the same pattern as the output of domestic producers is distributed. Applying national input coefficients to regions assumes a given industry in every region is equally dependent upon foreign sources of supply. This is almost certainly not so for industries proximate to seaports.

Perhaps the most problematical phase in attempting to deduce regional input-output flows from national I/O studies is found in the use location quotients (LQ's) to convert the borrowed national input pattern to deduce the regionally-supplied component. A location quotient is a measure of a region's self-sufficiency in some activity defined by

$$(1) \quad LQ_i^r = \frac{e_i^r/E^r}{e_i^n/E^n}$$

where e_i^r is a measure of the activity of the i th industry in region r

E^r is a measure of aggregate activity in region r

e_i^n is a measure of the activity of the i th industry nationally

E^n is a measure of aggregate activity nationally

Earnings or employment data are usually used to construct LQ's. If LQ_i^r is greater than one, then the output of the i th industry in the r th region is supposedly more than necessary to meet the needs of regional users and the excess is exported to other regions. If LQ is less than one, the assumption is made that using industries must be importing a portion that input.

Location quotients are next applied to national input coefficients to estimate regional procurement coefficients, as shown in equation (2).

$$(2) \quad \hat{r}_{ij} = LQ_i \cdot a_{ij}$$

where

\hat{r}_{ij} = estimated proportion of total output of the jth industry in the region which is delivered to the ith regional user

a_{ij} = national input coefficient of the ith industry acquired from the jth supplier

The most significant conclusion which may be drawn from the LQ procedure is that each industrial sector in an economy is either an export sector or it is not. The procedure does not permit any sector to be exporting its output and users of that product also importing it. This means there can be no cross-hauling of products or services among regions. This is contrary to general observation. The well-known dependence of the Washington aerospace industry upon imports of aerospace products (parts) from elsewhere while simultaneously exporting aerospace products (completed aircraft) is illustrative. The importation of fresh fruits and vegetables during the year while exporting the same products occurs because of seasonal differences in the maturation of crops. Tourism is still another illustration of cross-hauling.

Most relevant to the present inquiry, transport services, an important activity in every state, provide services to facilitate the export of goods to out-of-state purchasers. They also provide transshipment services by facilitating the movement of goods produced outside the state to users of those goods located outside the state. Furthermore, they provide transport services between producers and

customers located within the state. Finally, since Washington industries purchase inputs from suppliers elsewhere, including purchases from transport sectors elsewhere (the "purchasers pay the freight" rule), transport services are imported.

Simply put, transport services are both exported and imported, as well as providing local service.

The principal conclusion drawn from this brief methodological discussion is that neither field surveys of location quotient approaches can provide a satisfactory procedure for estimating the input-output patterns of regional transportation industries. Since the Rosetta stone for this purpose has yet to be discovered, the analysis in the following pages provides an approach to address the problem in a pragmatic fashion. In particular, the procedure attempts to identify levels of exports and imports of transportation industry services. Both turn out to be important to the Washington economy.

Defining the Transport Service Industry

For purposes of this study the Transportation Services sector is defined in accordance with the Standard Industrial Classification Manual (1972) to include "establishments providing to the general public or to other business enterprises passenger and freight transportation... and the U.S. Postal Services."

This definition of the Transportation Services sector includes all transport services provided for sale on a commercial basis, but excludes from its scope self-provided transportation (owner-operated trucks, buses, vessels, aircraft). It includes the U.S. Postal Service, water-related activities of public ports, marinas, ferries, public transport

and chartered buses (including contracted school business), but not school-provided bus transportation.

Excluded activities include self-provided transportation services by manufacturers (e.g., owner-operated vehicles) or households, government operated transport services provided without user charges, and public administration of transportation service activities by governments (e.g., Coast Guard, Sea-Tac Airport administration by Port of Seattle, Federal Aviation Administration).

Following the SIC system, elements of the Transportation Services sector are subdivided into major SIC groups as shown in Table 1. Also shown in this table are the corresponding I/O sector numbers assigned to these activities in the 58-sector Washington I/O model (See Appendix Table II for a complete listing of sectors). Hereafter, the designation "Transportation Services sector" or industry will refer to the combined modes of transport while sub-sectors will be designated by appropriate modifiers or I/O numbers.

Estimating Sector Outputs and Inputs

In principal, the gross output (or control total) of each sector should represent the sales, shipments, operating revenue, receipts, or margins earned which are related to the resources employed within the industry in Washington State. Such information is available for most sectors of the economy from the quinquennial industrial censuses.

TABLE 1

Modes of Transport in the Washington State Transport Model

<u>Brief Description</u>	<u>SIC Group</u>	<u>I/O Sector</u>
Railroad Transportation	40	43, includes AMTRAK
Local and Suburban Transit	41	44, includes public transit
Motor Freight & Warehousing	42	45
U.S. Postal Service	43	50
Water Transportation	44	46, includes ferries, public ports
Air Transportation	45	47
Pipelines	46	48
Transportation Services	47	49

However, the Census of Transportation for 1982 is a truck inventory and use survey. It provides information related to the physical condition and selected operational characteristics of the truck population but very little useful data for input-output studies. Compared to other sectors, the regional economic information system for the Transportation Services sector is nearly barren.

This study estimates the operating revenues for the various modes of transport using a variety of indirect estimation techniques. These estimates are, for the most part, based upon national revenue per employee or per dollar of payroll applied to the corresponding input variable in Washington State. The Washington Department of Revenue (DOR) gross income statistics have also been evaluated as a source for control totals but appear unsatisfactory for this purpose. This is because DOR reportedly includes in its gross income estimates all

revenues received by Washington transportation agencies regardless of place of activity. Another data source -- the Washington Public Utilities and Transportation Commission -- is fragmentary and generally does not identify regional operating revenue of important inter-state carriers.

The basis for estimating the operating revenues, value added, and the regional procurement pattern for each transportation sub-sector is summarized in the following sections.

Rail Transport, WAIO 43

The control total for the Washington Rail Transport sector is estimated to be \$640 million. This estimate was formed on the basis of national rail operating revenues (including AMTRAK) per dollar of wage disbursements applied to wage payments in Washington State. A similar estimate -- \$631 million -- is obtained by using national revenue of Class I railroads as reported by the Interstate Commerce Commission (Transport Statistics of the U.S., 1982). Track mileage ratios, sometimes used to estimate regional rail activity, provided higher estimates but are not deemed as useful an indicator for revenue estimation purposes.

The value-added component of operating revenues has been estimated as \$423 million based on the national value-added share calculated from the Yearbook of Railroad Facts (1982). Intermediate inputs from the USIO study for 1977 were used to estimate technical inputs, while procurement from Washington industries was initially estimated by taking into account the reported sales (from surveys) of other sectors to the Transport Services sector, and judgement. The final estimates of

regional inputs into the Rail Transport sector were modified in the balancing of the I/O table to achieve consistency among all sectors.

Passenger Transport, WAIO 44

Operating revenues of Passenger Transport Services were estimated from national revenue estimates and Washington employment and payrolls data. Various approximating methods yielded projections of Washington Passenger Transport operating revenues ranging from \$280 to \$407 million. An estimate of \$330 million was made, based on national bus revenue per employee applied to Washington State employment (including public employment) in this sector. Incorporated in this control total estimate are all commercially available motorized transport passenger service, including bus, taxi, and light rail (but excluding railroads) and contracted school busing. Self-operated transportation services by school districts or other government agencies, individuals, business firms, and other institutions are excluded.

Value-added is estimated to be \$200 million, based on the ratio of value-added to output as reported in the USIO study. Procurement estimates are based on the USIO study, the Transit Fact Book (American Public Transit Association), and National Transportation Statistics (U.S. Department of Transportation). Purchases from Washington suppliers were estimated on the basis of comments by two Washington passenger carriers and analysts' judgement, then adjusted to be consistent with the sales distribution of all other sectors in the balancing process.

Motor Freight, WAIO 45

This sector includes establishments primarily engaged in public transport of goods (common or contract carriers) and public warehousing. It does not include trucking or warehousing related to other businesses such as milk delivery or wholesale distributors.

Estimates of operating revenues were made by several procedures, separately for motor carriers and warehousing, using national operating revenue per employee or per dollar of payrolls, and Washington employment or payrolls data. These control total estimates ranged from \$1,089 to \$1,429 million. The estimate actually adopted is \$1,380 million, which is consistent with DOR revenue data.

The value-added estimate is based on the USIO/1977 study. The distribution of expenditures and regional procurement were made judgementally using USIO/1977 proportions and operating statistics of WUTC (Class I and Class II Motor Carriers of Property), and adjusted to be consistent with other sectors of the table in the balancing process.

Water Transportation, WAIO 46

Water transport is very significant in Washington State because of its large sea ports, and its ports upon the Columbia River. Private sector Water Transport in Washington accounts for 4.1% of national employment and 4.8% of national payrolls in that sector. Using the private sector payroll share applied to USIO output (projected to 1982) yields private sector operating income of \$1,296 million. Additionally, the output of this sector is defined to include the revenues of water related public port authorities of \$109 million (Governmental Finances, Vol. 4, No. 2, 1983) and operating revenues of the Washington State

Ferry System of \$45 million. The control total of all included activities in this sector is estimated to be \$1,450 million.

Inquiry made it apparent that the major water carriers could not identify outlays related to Washington-created transport services, and therefore the technical input distributions replicate that of USIO/1977. Regional purchase data for petroleum fuels, derived from the motor fuel distributions reported by the Washington Department of Licensing, aided in the distribution of in-state procurement, but other regional purchases were estimated judgementally.

Air Transportation, WAIO 47

Air Transportation Services includes the activities of certified and non-certified air carriers, airports, and airport terminal services. Absent relevant regional data to estimate regional operating revenues, the control total was estimated on the basis of national output per dollar of wage payments and Washington wage payments. This control total (\$918 million) was subsequently revised to \$1,151 in recognition of the large expenditures made by airlines for jet fuels (Department of Licensing) at Washington terminals. Other intermediate inputs were based on USIO/1977, and the purchases from within the region were judgementally estimated.

Pipelines, WAIO 48

Oil pipelines (Yellowstone, Olympic, Chevron) represent a relatively small activity in Washington State, involving but 87 employees. The operating revenues from within-state transmission services is estimated to be about \$34 million. Regional procurement is

based on national input coefficients and judgementally allocated between in-state and out-of-state.

Transportation Services, WAIO 49

This sector includes the activities of travel agencies, freight forwarders, transportation agents, and miscellaneous activities in support of actual transportation of goods or people. Operating revenues of \$197 million were estimated on the basis of national output per worker applied to Washington employment. In retrospect, this may be too low an estimate, given the labor and proprietor earnings for this sector as subsequently (August 1986) reported by the Bureau of Economic Analysis. As in other sectors, the procurement estimates are based on national coefficients and judgementally allocated between in-state and out-of-state suppliers.

U.S. Postal Services, WAIO 50

The control total for this segment of the Transportation Services industry is based on expenditures, as reported in Federal Expenditures by State for the Fiscal Year 1983 (Bureau of the Census, Office of Management and Budget). Employee compensation is taken as equivalent to value-added. The distribution of expenses is based on outlays reported by three district offices (Seattle, Tacoma, Spokane), while in-state purchases were judgementally allocated.

While the estimates of output and regional input for the components of the Transportation Services sector may appear to be ad hoc, substantial forbearance ought to be allowed in view of the shortcomings of regional statistical systems. Survey approaches, so

useful for most other sectors, appear unfruitful. This is because accounting systems in place do not match (for the most part) the geographic zone (Washington state) which is the center of interest in this regional study. While the estimates are crude, they are not without their redeeming features. One is that the estimates of regional inputs are confined by the estimate of total input. Another is that the analysts have considered each sector separately, so that for the combined Transportation Services sector the errors in the components will be partly offsetting. Third, the regional input estimates have been adjusted for consistency with the overall table so that some of the survey-validated flows to the Transportation Services sector become incorporated in the regional purchase estimates.

It is useful to recapitulate the estimates of output, value-added, jobs, and earnings for the Transportation Services sector. These estimates are shown in Table 2. Still further sector-by-sector linkages are shown in the Transport I/O Gross Flows Table, Appendix III of this report.

Sources of Revenue

The proceeding section of this report provides estimates of the operating revenues attributed to the resources engaged in the Transportation Sector within Washington State. But what are the sources of those revenues? Since "the purchaser pays the freight" is the input-output accounting rule, the question may be phrased another way: What are the transport costs to be charged to each Washington sector for the acquisition of goods it uses in production? How much does each sector "buy" from local transport providers, and how much is imported?

TABLE 2

**Estimates of Gross Output, Value Added, Jobs, and
Earnings in the Transportation Services Sectors, 1982**

<u>I/O Sector</u>	<u>Gross output (\$ millions)</u>	<u>Value Added (\$ millions)</u>	<u>Earnings¹ (\$ millions)</u>	<u>Jobs¹ (thousands)</u>
Rail, 43	\$ 640	\$ 423	\$ 247	7.8

Transportation Services, Total	\$5,517	\$2,859	\$2,122	80.7

¹BEA concepts; earnings include wages and salaries, other labor income, and proprietor income, and jobs include employees, self employed, and unpaid family workers. Both jobs and earnings include government activity transferred into these sectors.

Our experience has been that purchases of goods, producers of goods, and transportation agents, are unable to provide sufficient useful information to distribute regional transport costs. It is totally impractical, if not impossible, to use surveys on a systematic basis for determining regional transport outlays sector by sector.

Instead, an indirect procedure was used to estimate transport costs. The procedure involves three stages of calculation. First, total transport input costs were estimated by applying national transport cost coefficients to the value of output of each Washington industry. Next, the total transport costs were allocated regionally (in-state, out-of-state) according to the ratio of in-state purchases to total intermediate inputs. Third, estimates of the within region transport costs associated with imports were added. This estimate of total within-state transport expense was then inserted in each column of the regional input-output table, and other purchases reduced to accommodate these transportation costs within the control total constraint.

More specifically, the national transport input cost coefficients were borrowed from the USIO/1977 study, and applied to Washington output levels on a sector-by-sector basis, as shown in equation (3). This equation assumes that each sector's total transportation input costs per dollar of output in Washington are similar to the nation.

$$(3) \quad \hat{x}_{t,j}^w = a_{t,j}^{us} \cdot x_j^w$$

where $t = \text{transport sector}$
 $a_{t,j}^{\text{us}} = \text{national transport input cost coefficient for } j^{\text{th}}$
 industry
 $\hat{x}_{t,j}^w = \text{estimate of } j^{\text{th}} \text{ Washington industry transport}$
 charges

The transport costs for the j^{th} industry are then geographically distributed by the ratio of in-state to total intermediate purchases, or

$$(4) \quad \frac{\sum_{i=1}^{51} x_{i,j}^{w,w}}{\sum_{i=1}^{51} x_{i,j}^w} \cdot \hat{x}_{t,j}^w = \hat{x}_{t,j}^{w,w}$$

where $\sum_{i=1}^{51} x_{i,j}^{w,w} = \text{intermediate inputs from Washington suppliers}$

$\sum_{i=1}^{51} x_{i,j}^w = \text{intermediate inputs from all suppliers}$

$\hat{x}_{t,j}^{w,w} = \text{estimated Washington within-state transport costs}$
 $\text{on goods supplied by Washington producers}$

Equation 4 is an approximation of transport input cost on locally produced goods purchased by Washington industries. It assumes that in-state transport costs, relative to total transport costs estimated in equation (3), vary with the fraction of intermediate inputs purchased from within-state suppliers. While the assumption underlying equation (3) probably understates total transport costs incurred by Washington industries (because of the remoteness of Washington state from centers of national production), equation (4) probably has a bias in the opposite direction (because it assumes transport costs per dollar are the same on local purchases as imports).

The third stage in the analysis of transport costs involves an estimate of within-state transport costs associated with imported intermediate inputs acquired by various industries. Logically, a portion of the transport costs on imports into the state must be assumed to be provided by Washington transporters. This is so because a substantial portion of transport costs are associated with the make-up and break-up of movements at each end of the traffic flow. We have assumed that one-half of the transport costs on imports are associated with services provided by the Washington transportation industry. This "rule of one-half" may exaggerate the in-state transport service cost on imports. Application of a gravity flow model, in which distance is a variable, might improve upon the estimate procedure used here but would require further information on the specific origin of imports into each sector. The principle of including locally provided transport services on imported goods does appear to be correct, in line with the scheme outlined in Figure 1. Thus, total transport costs are those associated with internal movements of goods within Washington plus a fraction of the transport costs on imported goods, or

$$(5) \quad \hat{X}_{t,j}^{w,w} = \hat{X}_{t,j}^{w,w} + 1/2 [\hat{X}_{t,j}^w - \hat{X}_{t,j}^{w,w}]$$

The final step involved accommodating these costs in the regional input structure of each sector. Since the various inputs into each sector were initially estimated on a "costs of materials consumed" basis which includes freight, the transport input costs were accommodated by "backing out" these charges from the costs of other inputs. Generally, the transport costs were accommodated by a scalar adjustment (downward) of other inputs. Margin adjustments for the trade sector were made at the same time, and both the trade and transport adjustments were

combined with the balancing, or reconciliation, of the table. In this process the expertise or background knowledge of analysts, who carried out the initial analysis for individual industries, played an important role. That knowledge explains why Logging and Saw-mill sectors are reported to make unusually large purchases from truck transportation (contract trucking and logging provided by independent truckers), or why Aluminium makes large purchases from Railroads (movement of alumina from port of entry to interior mills).

In the process of estimating transport cost by mode, a variety of special sources were drawn upon which provided hints rather than firm statistics. For agriculture, a study entitled Transport Needs of Washington Agriculture (K.L. Casavant and Frank Dooley, Washington State University, 1983) was valuable. Unpublished tabulations from the 1982 Census of Transportation relating to origin and destination of selected commodities (physical flows) were useful, as well as the Statistical Yearbook of the Western Lumber Industry, and the Washington State Transport Plan Update 1983-1985. But clearly, relevant published information is in short supply, and the information available is far from ideal.

Distribution of Transport Charges to Final Markets

Since outlays for Washington transportation services by the intermediate sectors totaled \$1,361 million while operating revenues are calculated to be \$5,517 million, then \$4,156 million of revenues is a residual which can be attributed to final demand. Final demand includes outlays of Washington consumers, investment, state and local government, and export sales. The latter includes exports to the rest-of-the-U.S., foreign exports, and the geographically undefined federal government.

The allocation of Washington-supplied transport costs to consumer, state and local governments, and investment followed procedures similar to those described earlier. The remainder, amounting to \$3,279 million, is indicative of the transport revenues associated with exports, including transshipment services. While these distributions, shown in Table 3, are orders-of-magnitude estimates, the distribution to exogenous markets have no influence upon the estimated multipliers for the Transport Services sector or any other Washington industry.

TABLE 3

Estimated Sales of Washington Transportation
Service Sectors to Intermediate and Final Demand
(millions of dollars)

Sector Name	Intermediate Sales	Final Sales							Total FD
		PCE	WA S&L	WA GPDI	FED	EXP-US	EXP-FOR		
Total	\$1,361	754	100	23	85	2,666	528	4,156	
Rail	203	40	1	5	7	335	49	437	
Bus	36	172	65	-	1	25	1	264	
Truck	624	200	6	15	31	385	119	756	
Water	230	50	2	2	15	903	248	1,220	
Air	126	200	13	1	20	692	99	1,025	
Pipelines	6	7	-	-	1	19	1	28	
Services	36	10	1	-	-	140	10	161	
U.S. Post	100	75	12	-	10	167	1	265	

One impressive statistic stands out: the highly significant flow of total revenues of the Transport Services sectors associated with exports. Transport operating revenues associated with exports to the

rest-of-the-U.S. are estimated to be \$2,666 million, and those related to foreign exports are \$528 million. These important sources of the Washington transport system operating revenues are not really surprising to those familiar with the export-dependence of the industries within the Washington economy. Such export-oriented industries generate substantial traffic revenues for commodity carriers and for the arrangers of shipments (freight forwarders, shipping agents). Visible in the seaports, especially those of Seattle and Tacoma, are the cargo activities associated with the transshipments of commodities. Seattle is also a regional and international airline hub for both passenger and air freight services. The Washington Transportation Services sector is, indeed, an important "export sector" for the Washington economy.

The Washington Transport-Oriented Gross Flows Table

The Washington Transport-oriented Gross Flows Table, Appendix III, provides a detailed quantitative description of the transactions structure of the Washington economy, including the linkages between the Transportation Service sectors and others. Each column of the table shows the operating inputs acquired by each Washington industry from others within the state, the value-added by the resources employed within each industry, and its purchases from out-of-state suppliers. Each row of the table shows the Washington Markets of each sector and sales to final users.

Some highlights concerning the quantitative dimensions of the transport sectors -- believed to be reasonable approximations in terms of order-of-magnitude -- follows:

- The Transport Services sectors contributed nearly \$3 billion, or 4.9%, of the GSP created in Washington State during 1982.

The GSP originating (value-added created) within each sector of the transportation industry is shown in Table 5.

- The Transportation Services sectors are important markets for several Washington industries. They are a significant purchaser of the output of petroleum refiners, spending about \$664 million for fuels which represents about 14% of the output of the Petroleum sector. Service sector inputs into the Transportation sector were worth \$170 million. Lesser amounts were purchased from 35 of the other 48 sectors in the Washington state model.

- Every industrial sector in Washington depends, in varying degrees, upon Transportation Services. The leading transport-dependent industries are shown in Table 6.

- The Transportation Services sectors are important export sectors in the Washington economy, in that out-of-state users of the Washington transportation system contribute to its revenue. The export of transportation services (sales to rest-of-the-U.S., Exports-foreign, and sales to the Federal government) amounted to \$3.3 billion. These revenues are earned in the process of shipping Washington products to out-of-state customers, non-resident passenger services, and earnings from transshipments. The leading exporters of Transportation Services are shown in Table 7.

The export of Transportation Services accounted for 8% of total Washington State exports. Transportation Services accounted for about 6% of Washington's total foreign exports, and 11% of exports to the rest-of-the-U.S. The greater relative importance of the latter may be due to the greater inbound transshipments as compared to outbound.

Transportation Multipliers in the Washington Economy

From the Transportation I/O Gross Flows Table, Appendix III, it is possible to derive multipliers, by mode of transportation. Casual readers are warned that there are numerous multiplier concepts.

There is no such thing as "the" multiplier for an industry. There are different multipliers depending upon the form in which the multiplier is expressed, the range of repercussions encompassed by a multiplier model, and the particular theory (or theories) of interaction used to construct them.

In this presentation we avoid a technical discussion of all the options used in preparing multiplier estimates. Our discussion is limited to Leontief-type multipliers which measure the direct, indirect, and consumption-induced activity (called Type II multipliers). Even so, the size of such multipliers varies depending upon the particular variables in the numerator and denominator of multiplier ratios, and the particular theories of interaction used to derive them. A useful discussion of problems of this nature may be found in The Washington State Input-Output Study for 1982 (March, 1986).

Are Transportation Service Exports Exogenous?

Impact multipliers are postulated upon the export-base theory of regional change. This theory (briefly) argues that changes in exports of a sector leads endogenously to changes in the output of other sectors which supply inputs to the export industry. The ripple effects reverberate throughout the economy leading to a multiple expansion or contraction of output, employment, and income.

A representative I/O model used for the assessment of these impacts is of the form $X = (I - R)^{-1} Y$, where Y is a vector of final

demand (including exports), R is a regional direct input coefficient matrix, and $(I - R)^{-1}$ is the interaction matrix. Such a model constitutes the basic framework for the estimation of multipliers in this report.

In a typical application, the multipliers of the interaction matrix are applied to a change in exports of the i th sector to estimate the total impact upon other sectors of the economy. Ordinarily, the export demands are assumed to be exogenous, and independent of one another.

However, exports of the Transportation Services sectors are, at least in part, dependent upon the exports of some other sector(s). This means that, in the assessment of multiplier impacts, consideration should be given to the joint effects of the impacts of the exports of a given sector Y_i , and the transportation exports Y_t simultaneously induced.

Whether this bias in the measurement of impact multipliers is important or not is not ascertainable. In the context of all the other difficulties (both empirical and conceptual) associated with the estimation of multipliers perhaps it deserves to be an issue buried with others as a "noise" factor. On the other hand, given the importance of Transportation Service exports as revealed in this study (they constitute 8% of Washington exports) it does seem potentially significant.

One possible means of addressing this problem is to consider any export demand in two parts. The first would be the export demand for the output of the i th industry, while the second would be the associated

transport exports. The total impact would be the sum of both components.

Estimates of the Transportation Services Multipliers

From among the various versions of impact multipliers, three are presented in Table 8. These are the value-added (or GSP) multipliers, the earnings multipliers, and the jobs multipliers. The value-added variable is defined as GSP originating, inclusive of labor compensation, rent, interest, profits before taxes and capital consumption allowances. The earnings variable is defined as the income of labor (wage and salary payments and other labor income) and proprietors income net of capital consumption allowances. Jobs are defined to include full and part-time employees, unpaid family workers, and self-employed persons.

Since all the multipliers shown in this report are Type II, the issue of closure by which household consumption is made endogenous to the model is important. The underlying theory of income and consumption for each of the three sets of multipliers is made explicit in the following statements:

$$\text{Value-added multipliers: } VA_i = v_i(X_i), C_i = c_i(VA), c_i = \frac{C_i}{GSP}$$

$$\text{Earnings multipliers: } Earn_i = e_i(X_i), C_i = c_i(Earn), c_i = \frac{C_i}{YP}$$

$$\text{Jobs multipliers: } Jobs_i = j_i(X_i), C_i = c_i(Earn), c_i = \frac{C_i}{YP}$$

None of these formulations of the multipliers is fully satisfactory. The value-added multipliers tend to exaggerate the size of multipliers in some sectors and understate them in others. The reasons for this is the varying degree to which the value-added in different sectors is linked to consumer expenditures within Washington state. By contrast, the earnings and jobs multipliers are systematically understated since consumer spending coefficients are

ratios of consumption to personal income, rather than consumption to earnings. Unfortunately, no estimates of consumption uniquely related to earnings are available.

Not only are there different theories of model closure, but there are different methods of stating multiplier relationships. The sectoral multiplier tables in the Appendix tables show the direct, indirect, and induced impacts per million dollars of final demand. By dividing the total impact per million dollars of final demand by the direct impact per million of final demand, these are restated into a more conventional form of total impact per unit of direct impact.

For all transport modes, the value-added multiplier is \$2.03. This means that for each one dollar of value-added directly created by the export of transportation service there is, on the average an additional \$1.03 created in other sectors of the economy indirectly and thru induced spending by households. The Transportation Services sector value-added multipliers tend to be somewhat smaller than the average of all sectors of the economy combined (\$2.79); this is because the direct value-added (the denominator of the value-added multiplier) for the Transportation Services sector is relatively high. The multipliers for individual modes of transportation tend to cluster around the average for all transport sectors combined.

The earnings multiplier averages \$1.53 for Transportation Services, as compared with \$2.08 average for all industries. The Pipelines earnings multiplier is unusually high; this reflects the fact that there is no proprietor income in Pipelines (all Pipeline systems are corporate) and direct labor income earned in this sector is very small relative to its revenue. Again, small denominators make for large

multipliers. The reverse situation applies to the Mail (Postal Service) sector: direct labor costs are high relative to revenues, and hence a small multiplier.

Table 8

Transport Sector Multipliers, 1982 (Total impact per unit of direct impact for the named variables)			
<u>Sector</u>	<u>Value-added</u>	<u>Earnings</u>	<u>Jobs</u>
Rail	\$1.89	\$1.43	1.88
Bus	1.95	1.42	1.60
Truck	2.02	1.53	1.80
Water	2.14	1.56	2.13
Air	2.22	1.57	2.29
Pipelines	2.09	2.44	3.57
Services	2.00	1.45	1.58
Mail	<u>1.73</u>	<u>1.29</u>	<u>1.57</u>
All modes	\$2.03	\$1.53	1.86
All industries	2.79	2.08	2.73

again smaller than the all industry average of 2.73. The smallish multipliers for Bus (Passenger Transit) and for Mail result from the fact that these activities are labor intensive and, for Bus, a relatively large number of part-time jobs.

Caveats on the Use of Multipliers

There are many misconceptions about multipliers. Here are a few warnings that readers should consider.

1. There is no such thing as "the" multiplier for an industry. There are different multipliers depending upon the form in which the multiplier is expressed, the variable under consideration, the range of repercussions encompassed by the multiplier model, and the particular theory (or theories) of interaction used to construct them.
2. Multipliers for a variable can be made to look large or small depending on the unit of expression chosen for the denominator of the multiplier ratio. Jobs multipliers that express total jobs per direct job will be smaller (other things being equal) than multipliers that express jobs per million dollars of output exported.
3. It is often assumed that large multipliers mean large total economic impacts, forgetting that the size of impacts depends on both the size of the multiplier and the magnitude of the disturbance to be multiplied. Sectors with large multipliers are sometimes those in which significant market changes, such as changes in exports, are unlikely.
4. The size of the multiplier depends on the scope of interactions incorporated in the multiplier model. Multipliers with households endogenous will be larger than those that exclude the repercussions associated with household spending. Multipliers that include government spending or investment spending reactions will be larger still.
5. Avoid the pyramiding of multiplier impacts. Multipliers should be used to assess the impact of an event that is external to the multiplier process itself. Good examples include evaluating the

impacts of changes in exports, federal expenditures, and investment outlays.

6. Multipliers in static models are timeless. Production adjustments may take place in anticipation of changes in market demand; on the other hand, reaction lags may result in delayed multiplier responses.
7. Ready-made multipliers, such as those included in this report, are representative for establishments within each sector but are not applicable to any particular enterprise.
8. Multipliers in this study are applicable to the Washington economy, and not to its subdivisions (counties or cities).
9. Empirical estimates of multipliers are based on interindustry relationships observed in a particular historical context (in this case, 1982).

An enumeration of some of the common pitfalls associated with the use of multipliers may be helpful to readers, but in each potential application there is no substitute for sound economic analysis. That kind of analysis arises out of an understanding of the theoretical structure of input-output models in particular and economic analysis in general. Ready-made recipes are seldom applicable to particular instances that economists are called upon to analyze.

Positive uses of the Transport Services sector multipliers include the evaluation of the impacts of changes in the demand for transportation services. Examples which come readily to mind are:

- What is the impact upon the Washington economy of changes in operating revenue occasioned by the capture (or loss) of exports by this sector?

- If the regulatory environment should change the demand for transport services, how will the economy be effected? Which sectors will be effected most?
- What is the net effect upon each sector in the economy if one mode of transportation service displaces another?
- What are the effects of changes in the procurement patterns of the transportation modes (perhaps due to technology or price changes) upon other industries in the state?
- What happens to the demand for Transportation Services as a result of changes in the exports of other industries?
- What will be the impact upon the economy of the state as a result of new investment in the Transportation Services sector?

There are no simple answers to any of the above question; each requires ancillary analysis which may be rather involved. Yet, an input-output model of the kind developed here has been found to be the most effective instrument through which to examine the interindustry linkages which exist among industries, and to trace impacts of changes in one upon others. The Washington Transport-oriented Gross Flows Table, Appendix III, provides investigators with an empirical framework as a point of departure for analyzing interactions within the economy of the state.

Concluding Observations

The objective of this study has been to analyze the input-output structure of the Transportation Services industry in Washington state. The absence of a pre-existing conceptual framework applicable to the definition and measurement of output of the regional transportation

industries has complicated this endeavor. This report has drafted an analytical framework, consistent with the principles of regional accounting. This study also provides estimates of the sources of operating revenue and disposition of the outlays of the several modes of transport service. Much remains to be done to improve upon these estimates and the procedures used to make them. No apology needs to be made for the use of judgement when necessitated by the absence of quantitative evidence. The two-way (rows and columns) approach used in estimating transport sector flows imposes a discipline upon the process, but future improvements in statistical reporting of economic variables in the transport sectors could do much to further narrow the inevitable errors in the construction of the gross flows table.

Until regional analysts devote more of their ingenuity to addressing the specifics of regional accounting, regional input-output will become anchored to synthetic models which are empty of relevant definition, conceptually inappropriate, and empirically specious.
