This tutorial contains navigation buttons that enable you to move throughout the tutorial.

Please use the navigation buttons and not the page up/page down or arrow keys to navigate through the tutorials.

This is the 'Next' button. It takes you to the next frame or stop point.

This is the 'Previous' button. It takes you to the previous frame or stop point.

This is the 'Go to frame' button. It takes you to a specified frame.

This is the 'Go to URL' button. It takes you to a website link.

Press the 'Next' button below to start this tutorial.

This tutorial will cover how to import data from the Matlab workspace into the zcorrectorgui.

For this to work, the matlab variables containing the data must be named and formated exactly as shown in this tutorial. If they are not, the import will not work.

The zcorrectorgui works with peak area images selected and exported from the instrument software. It cannot read raw data and only works with peak area images.

Iontof users can export the data for each slice into .bif or .bif6 files and import them directly into the zcorrectorgui. This is described in the tutorial 'Zcorrectorgui_01_MainPage.pdf'.

PHI is working on an importer that will enable PHI users to get their data into matlab.

In the meantime, if you can get your data into Matlab and format it as described in this tutorial, you can import your data from the workspace and then use the zcorrectorgui.

Shortcuts How to Add What's New

Workspace

Base

Name	Value
activedata	<56x1 cell>
maxis	<8x8 char>

There are two required variables for the zcorrectorgui, activedata and maxis.

'activedata' is a cell array that contains the total counts image and peak area images for each slice in the depth profile.

'maxis' contains the masses of the selected peaks in a character array.

Each cell of 'activedata' contains the total counts image and peak area images for a slice from the depth profile. The slices are ordered as they were collected (cell 1 = slice 1 = first image set, cell 2 = slice 2 = second image set after first sputter cycle, etc). In this data set there are 56 slices.
The image matrixes in each cell are all in their folded form (pixel size x pixel size x #of images).
All image matrices for each slice are organized in this order:
totalcounts image
peak area image 1
peak area image 2
peak area image #....
The totalcounts image must be the first image in the stack.
'activedata' must be formated as 8bit unsigned integers (uint8). If it is not formatted this way you will not be able to use the zcorrectorgui. Unsigned integers are used to avoid memory issues in matlab.

>>
```

'maxis' contains the peak masses for the peaks used to create the peak area images in 'activedata'.

This variable must be formatted as a character array. If you import the peak masses into matlab you can covert them to characters by using the num2str function.
maxis = num2str(maxis);
